

PROJECTION METHOD WITH REAL OBJECT PROJECTOR

Background of Invention

5

1. Field of the Invention

The invention relates to a projection method with a real object projector, and more particularly, to a projection method which suitably magnifies a
10 projected image of a transparent film according to the transparent film type.

2. Description of the Prior Art

Projectors or projection tools are commonly used for displaying visual aids
15 during presentations or conferences

Fig.1 shows a conventional projector. An image apparatus 12 is installed on a base 10, and the image apparatus 12 includes an arm 14 and a lens 16. When projecting an object 18, the object 18 is placed under the lens 16, and the
20 lens 16 focuses on the object 18. A user can adjust the magnification of the image and adjust the focus with the lens 16 according to his requirements.

However, when a user needs to project a transparent film, the projector fails to project the transparent film, since a bottom light source is needed. An
25 extra light source module 20 is required for the projector to project the transparent film 22, as Fig.2 shows. Lacking a light source module 20 prevents

the projection of the transparent film 22.

The method of projecting a transparent film is by placing the transparent film 22 on top of the light source module 20, and under the lens 16 and 5 focusing the lens 16 on the transparent film 22. Then the user adjusts the projected image size and focus according to the size of the transparent film. When there is more than one size of transparent film 22, users need to continuously adjust the projected image size and focus according to the different transparent films 22. This is inconvenient and results in a poor quality 10 of presentation.

Therefore, there is need for an improved projection method with a real object projector to project kinds of transparent films.

15 - Summary of Invention

It is therefore an objective of the present invention to provide a projection method using a real object projector to solve the above-mentioned problems. A light source module is installed on a base of the real object projector to project 20 a transparent film. The projection method can optimally magnify images in accordance with various sizes of transparent films.

According to the claimed invention, A projection method of a real object projector which comprises a light source module that further includes a 25 transparent film clip having a mark, a control circuit and an image receiving apparatus comprise steps of: automatically or manually moving the image

receiving apparatus to a suitable position in accordance with the mark on the transparent film clip; then automatically or manually focusing the image receiving apparatus according to the transparent film clip; and pressing an image receiving key to magnify the projected image via a control circuit; or

5 automatically identifying the kind or type of transparent film and magnifying the projected image.

These and other objectives of the present invention will no doubt become obvious to those of ordinary skill in the art after reading the following detailed

10 description of the preferred embodiments that are illustrated in the various figures and drawings.

Brief Description of Drawings

Detailed Description

Fig.3 and Fig.4 are diagrams illustrating a real object projector which can
10 carry out a projection method according to the present invention. The real
object projector comprises a base 30 in which a control circuit is installed for
receiving and transferring the image data, and identifying and magnifying it.
An image receiving apparatus 32 is connected to the base 30. The image
receiving apparatus 32 comprises an arm 34 connected to the base 30 and a lens
15 module 36 installed on the arm 34. The arm 34 can be rotated in a limited angle
or range with a fulcrum connecting the arm 34 and the base 30. The lens
module 36 is used to capture an image. A light source module 38 is connected
to the base 30 by an axle 40. The light source module 38 can be rotated in a
limited angle with the axle 40 acting as a fulcrum. A damper can be further
20 installed on the axle 40 for buffering the rotation of the light source module 38.
Furthermore, the rotation of the light source module 38 can be operated
manually or automatically with a combination of a motor, a gear wheel, a rack,
a belt and so on. Further, as Fig.5 and Fig.6 show, the light source module 38
can be designed to be stored in the base 30 and be taken out from the base 30
25 by pulling or rotating. The pull or rotation operation can be manually operated
or automatically operated by a combination of a motor, a gear wheel, a rack, a

belt and so on.

Referring to the Fig.4 and Fig. 7, a transparent film 42 can be placed on the light source module 38 for projection, and can be installed in a transparent film clip 44 having a mark 46 and then be placed on the light source module 38 for projection. The transparent film clip 44 is variously installed in accordance with transparent films 42 of different sizes, and the marks 46 on different transparent film clips 44 are unique. The mark 46 is a positioning or locating mark and is also an identification mark for identifying the transparent film 42. The mark 46 can be at least one transparent opening, and the opening of each of the transparent film clip 44 has a different shape and number.

Fig.8 shows an embodiment of the present invention using the real object projector. Firstly, in step S10, the image receiving apparatus is manually or automatically moved to a suitable position in accordance with the mark. In step S12, the image receiving apparatus is manually or automatically focused corresponding to the transparent film clip. In step S14, pressing the image receiving key located on the real object projector or on a computer which is connected to the real object projector. Finally, in step S16, digitally magnifying the projection image of the transparent film with the control circuit corresponding to the type of transparent film clip. In above-mentioned step S14, the image receiving key is selected from an image receiving key which assigns the size of the transparent film and an image receiving key which does not assign the size of the transparent film. If the image receiving key is selected from the later, between steps S14 and S16, the control circuit will automatically identify kinds of transparent film according to the mark on the transparent film

clip. Step S14 can be further arranged before step S10, and the method is performed in the sequence of S14, S10, S12, and S16. This means pressing the image receiving key and automatically moving the image receiving apparatus to a suitable position, then automatically focusing and identifying the 5 transparent film, and automatically magnifying the projection image or projected image of the transparent film. Step S12 can be further arranged after step S16, and the method is performed in the sequence of S10, S14, S16, and S12. This means manually moving the image receiving apparatus to a suitable position and pressing the image receiving key which assigns the size of the 10 image, and automatically magnifying and manually focusing the projection image or projected image of the transparent film. Furthermore, the sequence of steps S12 and S14 can be exchanged, and the method is performed in the sequence of S10, S14, S12, and S16. This means manually moving the image receiving apparatus to a suitable position and pressing the image receiving key, 15 then automatically focusing and identifying the kind of transparent film, and automatically magnifying the projection image of the transparent film.

Referring to Fig.9, which is a diagram illustrating an embodiment of the projection method according to present invention. In step S20, the image receiving apparatus is manually moved to a suitable position in accordance 20 with the mark on the transparent film clip. In step S22, automatically focusing the image receiving apparatus. Finally, in steps S24 and S26, automatically identifying the kind of transparent film and digitally magnifying the projection image of the transparent film with the control circuit.

according to present invention. In this method, utilizing a change of distance u of the image receiving apparatus 32 and the transparent film 42 to magnifying the received image. Referring to Fig.11, in step S30, firstly pressing the image receiving key located on the real object projector or on a computer which is connected to the real object projector. In step S32, automatically moving the image receiving apparatus to a suitable distance for maximizing an image. Finally, in step S34, manually or automatically focusing the image receiving apparatus according to the transparent film clip. In the above-mentioned step S30, the image receiving key is selected from an image receiving key which assigns the size of the transparent film and an image receiving key which does not assign the size of the transparent film. If the image receiving key is selected from the later, three steps are added between steps S30 and S32. The three steps comprise: (a) automatically moving the image receiving apparatus to a suitable position in accordance with the mark; (b) automatically focusing the image receiving apparatus; and (c) automatically identifying the type of the transparent film clip with the control circuit.

Besides the above-mentioned methods, the projection method according to the present invention can be further aimed to kinds of transparent film. Moving the image receiving apparatus to a suitable position for obtaining a sufficient magnifying power, and automatically zooming and focusing the image receiving apparatus to magnify the projected image. Referring to Fig.12, in step S40, firstly pressing the image receiving key on the real object projector or a key on a computer which is connected to the real object projector. In step S42, automatically moving the image receiving apparatus to a suitable position in accordance with the mark on the transparent film clip. In step S44,

automatically focusing the image receiving apparatus according to the transparent film clip. In step S46, automatically identifying the kind or type of transparent film clip with the control circuit. Then in step S48, automatically moving the image receiving apparatus to a suitable position for obtaining a
5 sufficient magnifying power depending on the type of transparent film clip. Finally, in step S50, automatically zooming and focusing the image receiving apparatus to magnify a projection or projected image.

Those skilled in the art will readily observe that numerous modifications
10 and alterations of the device may be made while retaining the teachings of the invention. Accordingly, the above disclosure should be construed as limited only by the metes and bounds of the appended claims.
